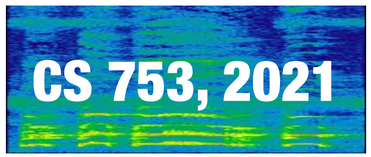
Language Models (II)

Lecture 5a



Instructor: Preethi Jyothi, IITB

Unseen Ngrams

Unseen Ngrams

- By using estimates based on counts from large text corpora, there will still be many unseen bigrams/trigrams at test time that never appear in the training corpus

Unseen Ngrams

- By using estimates based on counts from large text corpora, there will still be many unseen bigrams/trigrams at test time that never appear in the training corpus

- If any unseen Ngram appears in a test sentence, the sentence will be assigned probability 0

Unseen Ngrams

- By using estimates based on counts from large text corpora, there will still be many unseen bigrams/trigrams at test time that never appear in the training corpus

- If any unseen Ngram appears in a test sentence, the sentence will be assigned probability 0

- Problem with MLE estimates: Maximises the likelihood of the observed data by assuming anything unseen cannot happen and overfits to the training data

  - **Smoothing methods:** Reserve some probability mass to Ngrams that don’t occur in the training corpus

Add-one (Laplace) smoothing

Simple idea: Add one to all bigram counts. That means,

$$\Pr_{ML}(w_i|w_{i-1}) = \frac{\pi(w_{i-1}, w_i)}{\pi(w_{i-1})}$$

becomes

$$\Pr_{Lap}(w_i|w_{i-1}) = \frac{\pi(w_{i-1}, w_i) + 1}{\pi(w_{i-1}) + V}$$

where V is the vocabulary size

Example: Bigram counts

No smoothing

	i	want	to	eat	chinese	food	lunch	spend

Laplace smoothing moves too much probability mass to unseen events!

Add-α Smoothing

Instead of 1, add α < 1 to each count

$$\Pr_\alpha(w_i|w_{i-1}) = \frac{\pi(w_{i-1}, w_i) + \alpha}{\pi(w_{i-1}) + \alpha V}$$

Add-α Smoothing

Instead of 1, add α < 1 to each count

$$\Pr_\alpha(w_i|w_{i-1}) = \frac{\pi(w_{i-1}, w_i) + \alpha}{\pi(w_{i-1}) + \alpha V}$$

Choosing α:

- Train model on training set using different values of α
- Choose the value of α that minimizes cross entropy on the development set

Smoothing or discounting

- Smoothing can be viewed as **discounting** (lowering) some probability mass from seen Ngrams and redistributing discounted mass to unseen events

- i.e. probability of a bigram with Laplace smoothing

$$\Pr_{Lap}(w_i|w_{i-1}) = \frac{\pi(w_{i-1}, w_i) + 1}{\pi(w_{i-1}) + V}$$

- can be written as

$$\Pr_{Lap}(w_i|w_{i-1}) = \frac{\pi^*(w_{i-1}, w_i)}{\pi(w_{i-1})}$$

- where discounted count $\pi^*(w_{i-1}, w_i) = (\pi(w_{i-1}, w_i) + 1)\frac{\pi(w_{i-1})}{\pi(w_{i-1}) + V}$

Example: Bigram adjusted counts

No smoothing

	i	want	to	eat	chinese	food	lunch	spend

Problems with Add-α Smoothing

- What's wrong with add-α smoothing?

Problems with Add-α Smoothing

- What's wrong with add-α smoothing?
- Assigns too much probability mass away from seen Ngrams to unseen events

Problems with Add-α Smoothing

- What's wrong with add-α smoothing?
- Assigns too much probability mass away from seen Ngrams to unseen events
- Does not discount high counts and low counts correctly

Problems with Add-α Smoothing

- What's wrong with add-α smoothing?
- Assigns too much probability mass away from seen Ngrams to unseen events
- Does not discount high counts and low counts correctly
- Also, α is tricky to set

Problems with Add-α Smoothing

- What's wrong with add-α smoothing?
- Assigns too much probability mass away from seen Ngrams to unseen events
- Does not discount high counts and low counts correctly
- Also, α is tricky to set
- Is there a more principled way to do this smoothing?
  A solution: Good-Turing estimation

Advanced Smoothing Techniques

- Good-Turing Discounting
- Backoff and Interpolation
  - Katz Backoff Smoothing
  - Absolute Discounting Interpolation
- Kneser-Ney Smoothing

Good-Turing estimation (uses held-out data)

r	N_r	r* in heldout set	add-1 r*
1	2×10^6	0.448	2.8×10^{-11}
2	4×10^5	1.25	4.2×10^{-11}
3	2×10^5	2.24	5.7×10^{-11}
4	1×10^5	3.23	7.1×10^{-11}
5	7×10^4	4.21	8.5×10^{-11}

r = Count in a large corpus & N_r is the number of bigrams with r counts
r* is estimated on a *different* held-out corpus

[CG91]: Church and Gale, “A comparison of enhanced Good-Turing…”, CSL, 1991

Good-Turing estimation (uses held-out data)

r	N_r	r* in heldout set	add-1 r*
1	2×10^6	0.448	2.8×10^{-11}
2	4×10^5	1.25	4.2×10^{-11}
3	2×10^5	2.24	5.7×10^{-11}
4	1×10^5	3.23	7.1×10^{-11}
5	7×10^4	4.21	8.5×10^{-11}

r = Count in a large corpus & N_r is the number of bigrams with r counts
r* is estimated on a *different* held-out corpus

- Add-1 smoothing hugely overestimates fraction of unseen events
- Good-Turing estimation uses observed data to predict how to go from r to the heldout-r*

[CG91]: Church and Gale, “A comparison of enhanced Good-Turing…”, CSL, 1991

Good-Turing Estimation

- Intuition for Good-Turing estimation using leave-one-out validation:

Good-Turing Estimation

- Intuition for Good-Turing estimation using leave-one-out validation:
  - Let N_r be the number of words (tokens,bigrams,etc.) that occur *r* times

Good-Turing Estimation

- Intuition for Good-Turing estimation using leave-one-out validation:
  - Let N_r be the number of words (tokens,bigrams,etc.) that occur *r* times
  - Split a given set of N word tokens into a training set of (N-1) samples + 1 sample as the held-out set; repeat this process N times so that all N samples appear in the held-out set

Good-Turing Estimation

- Intuition for Good-Turing estimation using leave-one-out validation:
  - Let N_r be the number of words (tokens,bigrams,etc.) that occur *r* times
  - Split a given set of N word tokens into a training set of (N-1) samples + 1 sample as the held-out set; repeat this process N times so that all N samples appear in the held-out set
  - In what fraction of these N trials is the held-out word unseen during training?

Good-Turing Estimation

- Intuition for Good-Turing estimation using leave-one-out validation:
  - Let N_r be the number of words (tokens,bigrams,etc.) that occur *r* times
  - Split a given set of N word tokens into a training set of (N-1) samples + 1 sample as the held-out set; repeat this process N times so that all N samples appear in the held-out set
  - In what fraction of these N trials is the held-out word unseen during training?

    N_1/N

Good-Turing Estimation

- Intuition for Good-Turing estimation using leave-one-out validation:
  - Let N_r be the number of words (tokens,bigrams,etc.) that occur *r* times
  - Split a given set of N word tokens into a training set of (N-1) samples + 1 sample as the held-out set; repeat this process N times so that all N samples appear in the held-out set
  - In what fraction of these N trials is the held-out word unseen during training?

    N_1/N

Good-Turing Estimation

- Intuition for Good-Turing estimation using leave-one-out validation:
  - Let N_r be the number of words (tokens,bigrams,etc.) that occur *r* times
  - Split a given set of N word tokens into a training set of (N-1) samples + 1 sample as the held-out set; repeat this process N times so that all N samples appear in the held-out set
  - In what fraction of these N trials is the held-out word unseen during training?

    N_1/N
  - In what fraction of these N trials is the held-out word seen exactly k times during training?

Good-Turing Estimation

- Intuition for Good-Turing estimation using leave-one-out validation:
  - Let N_r be the number of words (tokens,bigrams,etc.) that occur *r* times
  - Split a given set of N word tokens into a training set of (N-1) samples + 1 sample as the held-out set; repeat this process N times so that all N samples appear in the held-out set
  - In what fraction of these N trials is the held-out word unseen during training?

    N_1/N
  - In what fraction of these N trials is the held-out word seen exactly k times during training? $(k+1)N_{k+1}/N$

Good-Turing Estimation

- Intuition for Good-Turing estimation using leave-one-out validation:
  - Let N_r be the number of words (tokens,bigrams,etc.) that occur *r* times
  - Split a given set of N word tokens into a training set of (N-1) samples + 1 sample as the held-out set; repeat this process N times so that all N samples appear in the held-out set
  - In what fraction of these N trials is the held-out word unseen during training?

    N_1/N
  - In what fraction of these N trials is the held-out word seen exactly k times during training? $(k+1)N_{k+1}/N$
  - There are ($\cong$)N_k words with training count k.

$S_k = \{$ set of all word types each of which occurs k times $\}$

$N_k = |S_k|$

Good-Turing Estimation

- Intuition for Good-Turing estimation using leave-one-out validation:
  - Let N_r be the number of words (tokens,bigrams,etc.) that occur *r* times
  - Split a given set of N word tokens into a training set of (N-1) samples + 1 sample as the held-out set; repeat this process N times so that all N samples appear in the held-out set
  - In what fraction of these N trials is the held-out word unseen during training?

    N_1/N
  - In what fraction of these N trials is the held-out word seen exactly k times during training? $(k+1)N_{k+1}/N$
  - There are ($\cong$)N_k words with training count k.
    - Probability of each being chosen as held-out:

Good-Turing Estimation

- Intuition for Good-Turing estimation using leave-one-out validation:
  - Let N_r be the number of words (tokens,bigrams,etc.) that occur *r* times
  - Split a given set of N word tokens into a training set of (N-1) samples + 1 sample as the held-out set; repeat this process N times so that all N samples appear in the held-out set
  - In what fraction of these N trials is the held-out word unseen during training?

    N_1/N
  - In what fraction of these N trials is the held-out word seen exactly k times during training? $(k+1)N_{k+1}/N$
  - There are ($\cong$)N_k words with training count k.
    - Probability of each being chosen as held-out: $(k+1)N_{k+1}/(N \times N_k)$

Good-Turing Estimation

- Intuition for Good-Turing estimation using leave-one-out validation:
  - Let N_r be the number of words (tokens,bigrams,etc.) that occur *r* times
  - Split a given set of N word tokens into a training set of (N-1) samples + 1 sample as the held-out set; repeat this process N times so that all N samples appear in the held-out set
  - In what fraction of these N trials is the held-out word unseen during training?

    N_1/N
  - In what fraction of these N trials is the held-out word seen exactly k times during training? $(k+1)N_{k+1}/N$
  - There are ($\cong$)N_k words with training count k.
    - Probability of each being chosen as held-out: $(k+1)N_{k+1}/(N \times N_k)$
  - Expected count of each of the N_k words in a corpus of size N: $\mathbf{k^* = \theta(k) = (k+1)\, N_{k+1}/N_k}$

Good-Turing Estimates

r	N_r	r*-GT	r*-heldout
0	7.47×10^{10}	.0000270	.0000270
1	2×10^{6}	0.446	0.448
2	4×10^{5}	1.26	1.25
3	2×10^{5}	2.24	2.24
4	1×10^{5}	3.24	3.23
5	7×10^{4}	4.22	4.21
6	5×10^{4}	5.19	5.23
7	3.5×10^{4}	6.21	6.21
8	2.7×10^{4}	7.24	7.21
9	2.2×10^{4}	8.25	8.26

Table showing frequencies of bigrams from 0 to 9
In this example, for $r > 0$, r*-GT $\cong$ r*-heldout and r*-GT is always less than r

[CG91]: Church and Gale, “A comparison of enhanced Good-Turing…”, CSL, 1991

Good-Turing Smoothing

- Thus, Good-Turing smoothing states that for any Ngram that occurs r times, we should use an adjusted count $r^* = \theta(r) = (r + 1)N_{r+1}/N_r$

Good-Turing Smoothing

- Thus, Good-Turing smoothing states that for any Ngram that occurs r times, we should use an adjusted count $r^* = \theta(r) = (r + 1)N_{r+1}/N_r$

- Good-Turing smoothed counts for unseen events: $\theta(0) = N_1/N_0$

Good-Turing Smoothing

- Thus, Good-Turing smoothing states that for any Ngram that occurs r times, we should use an adjusted count $r^* = \theta(r) = (r + 1)N_{r+1}/N_r$
- Good-Turing smoothed counts for unseen events: $\theta(0) = N_1/N_0$
- Example: 10 bananas, 5 apples, 2 papayas, 1 melon, 1 guava, 1 pear
  - How likely are we to see a guava next? The GT estimate is $\theta(1)/N$
  - Here, $N = 20$, $N_2 = 1$, $N_1 = 3$. Computing $\theta(1)$: $\theta(1) = 2 \times 1/3 = 2/3$
  - Thus, $Pr_{GT}(\text{guava}) = \theta(1)/20 = 1/30 = 0.0333$

Good-Turing Estimation

- One issue: For large r, many instances of $N_{r+1} = 0$!
  - This would lead to $\theta(r) = (r + 1)N_{r+1}/N_r$ being set to 0.

Good-Turing Estimation

- One issue: For large r, many instances of $N_{r+1} = 0$!
  - This would lead to $\theta(r) = (r + 1)N_{r+1}/N_r$ being set to 0.
- Solution: Discount only for small counts $r <= k$ (e.g. $k = 9$) and $\theta(r) = r$ for $r > k$

Good-Turing Estimation

- One issue: For large r, many instances of $N_{r+1} = 0$!
  - This would lead to $\theta(r) = (r + 1)N_{r+1}/N_r$ being set to 0.
- Solution: Discount only for small counts r <= k (e.g. k = 9) and $\theta(r) = r$ for $r > k$
- Another solution: Smooth N_r using a best-fit power law once counts start getting small

Good-Turing Estimation

- One issue: For large r, many instances of $N_{r+1} = 0$!
  - This would lead to $\theta(r) = (r + 1)N_{r+1}/N_r$ being set to 0.
- Solution: Discount only for small counts r <= k (e.g. k = 9) and $\theta(r) = r$ for $r > k$
- Another solution: Smooth N_r using a best-fit power law once counts start getting small
- Good-Turing smoothing tells us how to discount some probability mass to unseen events. Could we redistribute this mass across observed counts of lower-order Ngram events?

Advanced Smoothing Techniques

- Good-Turing Discounting
- Backoff and Interpolation
  - Katz Backoff Smoothing
  - Absolute Discounting Interpolation
- Kneser-Ney Smoothing

Backoff and Interpolation

Backoff and Interpolation

- General idea: It helps to use lesser context to generalise for contexts that the model doesn’t know enough about

Backoff and Interpolation

- General idea: It helps to use lesser context to generalise for contexts that the model doesn’t know enough about

- **Backoff**:

  - Use trigram probabilities if there is sufficient evidence

  - Else use bigram or unigram probabilities

Backoff and Interpolation

- General idea: It helps to use lesser context to generalise for contexts that the model doesn’t know enough about
- **Backoff**:
  - Use trigram probabilities if there is sufficient evidence
  - Else use bigram or unigram probabilities
- **Interpolation**
  - Mix probability estimates combining trigram, bigram and unigram counts

Interpolation

Interpolation

- Linear interpolation: Linear combination of different Ngram models

Interpolation

- Linear interpolation: Linear combination of different Ngram models

$$\begin{aligned}\hat{P}(w_n|w_{n-2}w_{n-1}) &= \lambda_1 P(w_n|w_{n-2}w_{n-1}) \\ &\quad +\lambda_2 P(w_n|w_{n-1}) \\ &\quad +\lambda_3 P(w_n)\end{aligned}$$

where $\lambda_1 + \lambda_2 + \lambda_3 = 1$

Interpolation

- Linear interpolation: Linear combination of different Ngram models

$$\begin{aligned}\hat{P}(w_n|w_{n-2}w_{n-1}) &= \lambda_1 P(w_n|w_{n-2}w_{n-1}) \\ &\quad +\lambda_2 P(w_n|w_{n-1}) \\ &\quad +\lambda_3 P(w_n)\end{aligned}$$

where $\lambda_1 + \lambda_2 + \lambda_3 = 1$

How to set the λ's?

Interpolation

- Linear interpolation: Linear combination of different Ngram models

$$\begin{aligned}\hat{P}(w_n|w_{n-2}w_{n-1}) &= \lambda_1 P(w_n|w_{n-2}w_{n-1}) \\ &\quad +\lambda_2 P(w_n|w_{n-1}) \\ &\quad +\lambda_3 P(w_n)\end{aligned}$$

where $\lambda_1 + \lambda_2 + \lambda_3 = 1$

1. Estimate N-gram probabilities on a training set.

2. Then, search for λ's that maximises the probability of a held-out set

- Backoff and Interpolation
  - Katz Backoff Smoothing
  - Absolute Discounting Interpolation
- Kneser-Ney Smoothing

Katz Smoothing

- Good-Turing discounting determines the volume of probability mass that is allocated to unseen events
- Katz Smoothing distributes this remaining mass proportionally across “smaller” Ngrams
  - i.e. no trigram found, use backoff probability of bigram and if no bigram found, use backoff probability of unigram

Katz Backoff Smoothing

- For a Katz bigram model, let us define:
  - $\Psi(w_{i-1}) = \{w: \pi(w_{i-1},w) > 0\}$
- A bigram model with Katz smoothing can be written in terms of a unigram model as follows:

$$P_{\text{Katz}}(w_i|w_{i-1}) = \begin{cases} \frac{\pi^*(w_{i-1},w_i)}{\pi(w_{i-1})} & \text{if } w_i \in \Psi(w_{i-1}) \\ \alpha(w_{i-1}) P_{\text{Katz}}(w_i) & \text{if } w_i \notin \Psi(w_{i-1}) \end{cases}$$

$$\text{where} \quad \alpha(w_{i-1}) = \frac{\left(1 - \sum_{w \in \Psi(w_{i-1})} \frac{\pi^*(w_{i-1},w)}{\pi(w_{i-1})}\right)}{\sum_{w_i \notin \Psi(w_{i-1})} P_{\text{Katz}}(w_i)}$$

Katz Backoff Smoothing

$$P_{\text{Katz}}(w_i|w_{i-1}) = \begin{cases} \frac{\pi^*(w_{i-1},w_i)}{\pi(w_{i-1})} & \text{if } w_i \in \Psi(w_{i-1}) \\ \alpha(w_{i-1})P_{\text{Katz}}(w_i) & \text{if } w_i \notin \Psi(w_{i-1}) \end{cases}$$

$$\text{where} \quad \alpha(w_{i-1}) = \frac{\left(1 - \sum_{w \in \Psi(w_{i-1})} \frac{\pi^*(w_{i-1},w)}{\pi(w_{i-1})}\right)}{\sum_{w_i \notin \Psi(w_{i-1})} P_{\text{Katz}}(w_i)}$$

Katz Backoff Smoothing

$$P_{\text{Katz}}(w_i|w_{i-1}) = \begin{cases} \frac{\pi^*(w_{i-1},w_i)}{\pi(w_{i-1})} & \text{if } w_i \in \Psi(w_{i-1}) \\ \alpha(w_{i-1})P_{\text{Katz}}(w_i) & \text{if } w_i \notin \Psi(w_{i-1}) \end{cases}$$

$$\text{where} \quad \alpha(w_{i-1}) = \frac{\left(1 - \sum_{w \in \Psi(w_{i-1})} \frac{\pi^*(w_{i-1},w)}{\pi(w_{i-1})}\right)}{\sum_{w_i \notin \Psi(w_{i-1})} P_{\text{Katz}}(w_i)}$$

- A bigram with a non-zero count is discounted using Good-Turing estimation

Katz Backoff Smoothing

$$P_{\text{Katz}}(w_i|w_{i-1}) = \begin{cases} \frac{\pi^*(w_{i-1},w_i)}{\pi(w_{i-1})} & \text{if } w_i \in \Psi(w_{i-1}) \\ \alpha(w_{i-1})P_{\text{Katz}}(w_i) & \text{if } w_i \notin \Psi(w_{i-1}) \end{cases}$$

$$\text{where} \quad \alpha(w_{i-1}) = \frac{\left(1 - \sum_{w \in \Psi(w_{i-1})} \frac{\pi^*(w_{i-1},w)}{\pi(w_{i-1})}\right)}{\sum_{w_i \notin \Psi(w_{i-1})} P_{\text{Katz}}(w_i)}$$

Katz Backoff Smoothing

$$P_{\text{Katz}}(w_i|w_{i-1}) = \begin{cases} \frac{\pi^*(w_{i-1},w_i)}{\pi(w_{i-1})} & \text{if } w_i \in \Psi(w_{i-1}) \\ \alpha(w_{i-1}) P_{\text{Katz}}(w_i) & \text{if } w_i \notin \Psi(w_{i-1}) \end{cases}$$

$$\sum_{w_i} P_{\text{Katz}}(w_i|w_{i-1}) = 1$$

$$\text{where} \quad \alpha(w_{i-1}) = \frac{\left(1 - \sum_{w \in \Psi(w_{i-1})} \frac{\pi^*(w_{i-1},w)}{\pi(w_{i-1})}\right)}{\sum_{w_i \notin \Psi(w_{i-1})} P_{\text{Katz}}(w_i)}$$

- A bigram with a non-zero count is discounted using Good-Turing estimation
- The left-over probability mass from discounting for the unigram model …
- … is distributed over $w_i \notin \Psi(w_{i-1})$ proportionally to $P_{\text{Katz}}(w_i)$

Advanced Smoothing Techniques

- Good-Turing Discounting
- Backoff and Interpolation
  - Katz Backoff Smoothing
  - Absolute Discounting Interpolation
- Kneser-Ney Smoothing

Recall Good-Turing estimates

r	N_r	θ(r)
0	7.47×10^{10}	.0000270
1	2×10^{6}	0.446
2	4×10^{5}	1.26
3	2×10^{5}	2.24
4	1×10^{5}	3.24
5	7×10^{4}	4.22
6	5×10^{4}	5.19
7	3.5×10^{4}	6.21
8	2.7×10^{4}	7.24
9	2.2×10^{4}	8.25

For $r > 0$, we observe that $\theta(r) \cong r - 0.75$ i.e. an absolute discounting

[CG91]: Church and Gale, “A comparison of enhanced Good-Turing…”, CSL, 1991

Absolute Discounting Interpolation

- Absolute discounting motivated by Good-Turing estimation
- Just subtract a constant d from the non-zero counts to get the discounted count
- Also involves linear interpolation with lower-order models

$$\Pr_{\text{abs}}(w_i|w_{i-1}) = \frac{\max\{\pi(w_{i-1}, w_i) - d, 0\}}{\pi(w_{i-1})} + \lambda(w_{i-1})\Pr(w_i)$$

Advanced Smoothing Techniques

- Good-Turing Discounting
- Backoff and Interpolation
  - Katz Backoff Smoothing
  - Absolute Discounting Interpolation
- Kneser-Ney Smoothing

Kneser-Ney discounting

$$\Pr_{\mathrm{KN}}(w_i|w_{i-1}) = \frac{\max\{\pi(w_{i-1}, w_i) - d, 0\}}{\pi(w_{i-1})} + \lambda_{\mathrm{KN}}(w_{i-1})\Pr_{\mathrm{cont}}(w_i)$$

Kneser-Ney discounting

$$\Pr_{\mathrm{KN}}(w_i|w_{i-1}) = \frac{\max\{\pi(w_{i-1}, w_i) - d, 0\}}{\pi(w_{i-1})} + \lambda_{\mathrm{KN}}(w_{i-1})\Pr_{\mathrm{cont}}(w_i)$$

c.f., absolute discounting

$$\Pr_{\mathrm{abs}}(w_i|w_{i-1}) = \frac{\max\{\pi(w_{i-1}, w_i) - d, 0\}}{\pi(w_{i-1})} + \lambda(w_{i-1})\Pr(w_i)$$

Kneser-Ney discounting

$$\Pr_{\mathrm{KN}}(w_i|w_{i-1}) = \frac{\max\{\pi(w_{i-1}, w_i) - d, 0\}}{\pi(w_{i-1})} + \lambda_{\mathrm{KN}}(w_{i-1})\Pr_{\mathrm{cont}}(w_i)$$

c.f., absolute discounting

$$\Pr_{\mathrm{abs}}(w_i|w_{i-1}) = \frac{\max\{\pi(w_{i-1}, w_i) - d, 0\}}{\pi(w_{i-1})} + \lambda(w_{i-1})\Pr(w_i)$$

Kneser-Ney discounting

$$\Pr_{\mathrm{KN}}(w_i|w_{i-1}) = \frac{\max\{\pi(w_{i-1}, w_i) - d, 0\}}{\pi(w_{i-1})} + \lambda_{\mathrm{KN}}(w_{i-1})\Pr_{\mathrm{cont}}(w_i)$$

Consider an example: "*Today I cooked some yellow curry*"

c.f., absolute discounting

$$\Pr_{\mathrm{abs}}(w_i|w_{i-1}) = \frac{\max\{\pi(w_{i-1}, w_i) - d, 0\}}{\pi(w_{i-1})} + \lambda(w_{i-1})\Pr(w_i)$$

Kneser-Ney discounting

$$\Pr_{\mathrm{KN}}(w_i|w_{i-1}) = \frac{\max\{\pi(w_{i-1}, w_i) - d, 0\}}{\pi(w_{i-1})} + \lambda_{\mathrm{KN}}(w_{i-1})\Pr_{\mathrm{cont}}(w_i)$$

Consider an example: "*Today I cooked some yellow curry*"

Suppose π(*yellow, curry*) = 0. $\Pr_{\mathrm{abs}}[w \mid \textit{yellow}] = \lambda(\textit{yellow})\Pr(w)$

c.f., absolute discounting

$$\Pr_{\mathrm{abs}}(w_i|w_{i-1}) = \frac{\max\{\pi(w_{i-1}, w_i) - d, 0\}}{\pi(w_{i-1})} + \lambda(w_{i-1})\Pr(w_i)$$

Kneser-Ney discounting

$$\Pr_{\mathrm{KN}}(w_i|w_{i-1}) = \frac{\max\{\pi(w_{i-1}, w_i) - d, 0\}}{\pi(w_{i-1})} + \lambda_{\mathrm{KN}}(w_{i-1})\Pr_{\mathrm{cont}}(w_i)$$

Consider an example: "*Today I cooked some yellow curry*"

Suppose π(*yellow, curry*) = 0. $\Pr_{\mathrm{abs}}[w \mid \textit{yellow}] = \lambda(\textit{yellow})\Pr(w)$

Now, say Pr[*Francisco*] >> Pr[*curry*], as *San Francisco* is very common in our corpus.

c.f., absolute discounting

$$\Pr_{\mathrm{abs}}(w_i|w_{i-1}) = \frac{\max\{\pi(w_{i-1}, w_i) - d, 0\}}{\pi(w_{i-1})} + \lambda(w_{i-1})\Pr(w_i)$$

Kneser-Ney discounting

$$\Pr_{\mathrm{KN}}(w_i|w_{i-1}) = \frac{\max\{\pi(w_{i-1}, w_i) - d, 0\}}{\pi(w_{i-1})} + \lambda_{\mathrm{KN}}(w_{i-1})\Pr_{\mathrm{cont}}(w_i)$$

Consider an example: "*Today I cooked some yellow curry*"

Suppose π(*yellow, curry*) = 0. $\Pr_{\mathrm{abs}}[w \mid \textit{yellow}] = \lambda(\textit{yellow})\Pr(w)$

Now, say Pr[*Francisco*] >> Pr[*curry*], as *San Francisco* is very common in our corpus.

But *Francisco* is not as common a "continuation" (follows only *San*) as *curry* is (*red curry, chicken curry*, *potato curry*, …)

c.f., absolute discounting

$$\Pr_{\mathrm{abs}}(w_i|w_{i-1}) = \frac{\max\{\pi(w_{i-1}, w_i) - d, 0\}}{\pi(w_{i-1})} + \lambda(w_{i-1})\Pr(w_i)$$

Kneser-Ney discounting

$$\Pr_{\text{KN}}(w_i|w_{i-1}) = \frac{\max\{\pi(w_{i-1}, w_i) - d, 0\}}{\pi(w_{i-1})} + \lambda_{\text{KN}}(w_{i-1})\Pr_{\text{cont}}(w_i)$$

Consider an example: "*Today I cooked some yellow curry*"

Suppose π(*yellow, curry*) = 0. $\Pr_{\text{abs}}[w \mid \textit{yellow}] = \lambda(\textit{yellow})\Pr(w)$

Now, say Pr[*Francisco*] >> Pr[*curry*], as *San Francisco* is very common in our corpus.

But *Francisco* is not as common a "continuation" (follows only *San*) as *curry* is (*red curry, chicken curry*, *potato curry*, …)

Moral: Should use probability of being a continuation!

c.f., absolute discounting

$$\Pr_{\text{abs}}(w_i|w_{i-1}) = \frac{\max\{\pi(w_{i-1}, w_i) - d, 0\}}{\pi(w_{i-1})} + \lambda(w_{i-1})\Pr(w_i)$$

Kneser-Ney discounting

$$\Pr_{\mathrm{KN}}(w_i|w_{i-1}) = \frac{\max\{\pi(w_{i-1}, w_i) - d, 0\}}{\pi(w_{i-1})} + \lambda_{\mathrm{KN}}(w_{i-1})\Pr_{\mathrm{cont}}(w_i)$$

c.f., absolute discounting

$$\Pr_{\mathrm{abs}}(w_i|w_{i-1}) = \frac{\max\{\pi(w_{i-1}, w_i) - d, 0\}}{\pi(w_{i-1})} + \lambda(w_{i-1})\Pr(w_i)$$

Kneser-Ney discounting

$$\Pr_{\mathrm{KN}}(w_i|w_{i-1}) = \frac{\max\{\pi(w_{i-1}, w_i) - d, 0\}}{\pi(w_{i-1})} + \lambda_{\mathrm{KN}}(w_{i-1})\Pr_{\mathrm{cont}}(w_i)$$

$$\Pr_{\mathrm{cont}}(w_i) = \frac{|\Phi(w_i)|}{|B|}$$

Ngram models as WFSAs

- With no optimizations, an Ngram over a vocabulary of V words defines a WFSA with V^{N-1} states and V^N edges.

- Example: Consider a trigram model for a two-word vocabulary, A B.
  - 4 states representing bigram histories, A_A, A_B, B_A, B_B
  - 8 arcs transitioning between these states

- Clearly not practical when V is large.
  - Resort to backoff language models

WFSA for backoff language model
